Average Rating: 3.89 (107 votes)

Design and implement a data structure for [Least Recently Used \(LRU\) cache](#). It should support the following operations: `get` and `put`.

`get(key)` - Get the value (will always be positive) of the key if the key exists in the cache, otherwise return -1.

`put(key, value)` - Set or insert the value if the key is not already present. When the cache reached its capacity, it should invalidate the least recently used item before inserting a new item.

The cache is initialized with a **positive** capacity.

Follow up:

Could you do both operations in **O(1)** time complexity?

Example:

```
LRUCache cache = new LRUCache( 2 /* capacity */ );

cache.put(1, 1);
cache.put(2, 2);
cache.get(1);    // returns 1
cache.put(3, 3);  // evicts key 2
cache.get(2);     // returns -1 (not found)
cache.put(4, 4);  // evicts key 1
cache.get(1);     // returns -1 (not found)
cache.get(3);     // returns 3
cache.get(4);     // returns 4
```

Solution

Approach 1: Ordered dictionary

Intuition

We're asked to implement [the structure](#) which provides the following operations in $\mathcal{O}(1)$ time :

- Get the key / Check if the key exists
- Put the key
- Delete the first added key

The first two operations in $\mathcal{O}(1)$ time are provided by the standard hashmap, and the last one - by linked list.

There is a structure called *ordered dictionary*, it combines behind both hashmap and linked list. In Python this structure is called *OrderedDict* and in Java *LinkedHashMap*.

Let's use this structure here.

Implementation

JavaPythonCopy

```
10 def get(self, key):
11     """
12     :type key: int
13     :rtype: int
14     """
15     if key not in self:
16         return - 1
17
18     self.move_to_end(key)
19     return self[key]
20
21 def put(self, key, value):
22     """
23     :type key: int
24     :type value: int
25     :rtype: void
26     """
27     if key in self:
28         self.move_to_end(key)
29     self[key] = value
30     if len(self) > self.capacity:
31         self.popitem(last = False)
32
33 # Your LRUCache object will be instantiated and called as such:
34 # obj = LRUCache(capacity)
35 # param_1 = obj.get(key)
36 # obj.put(key,value)
```

Complexity Analysis

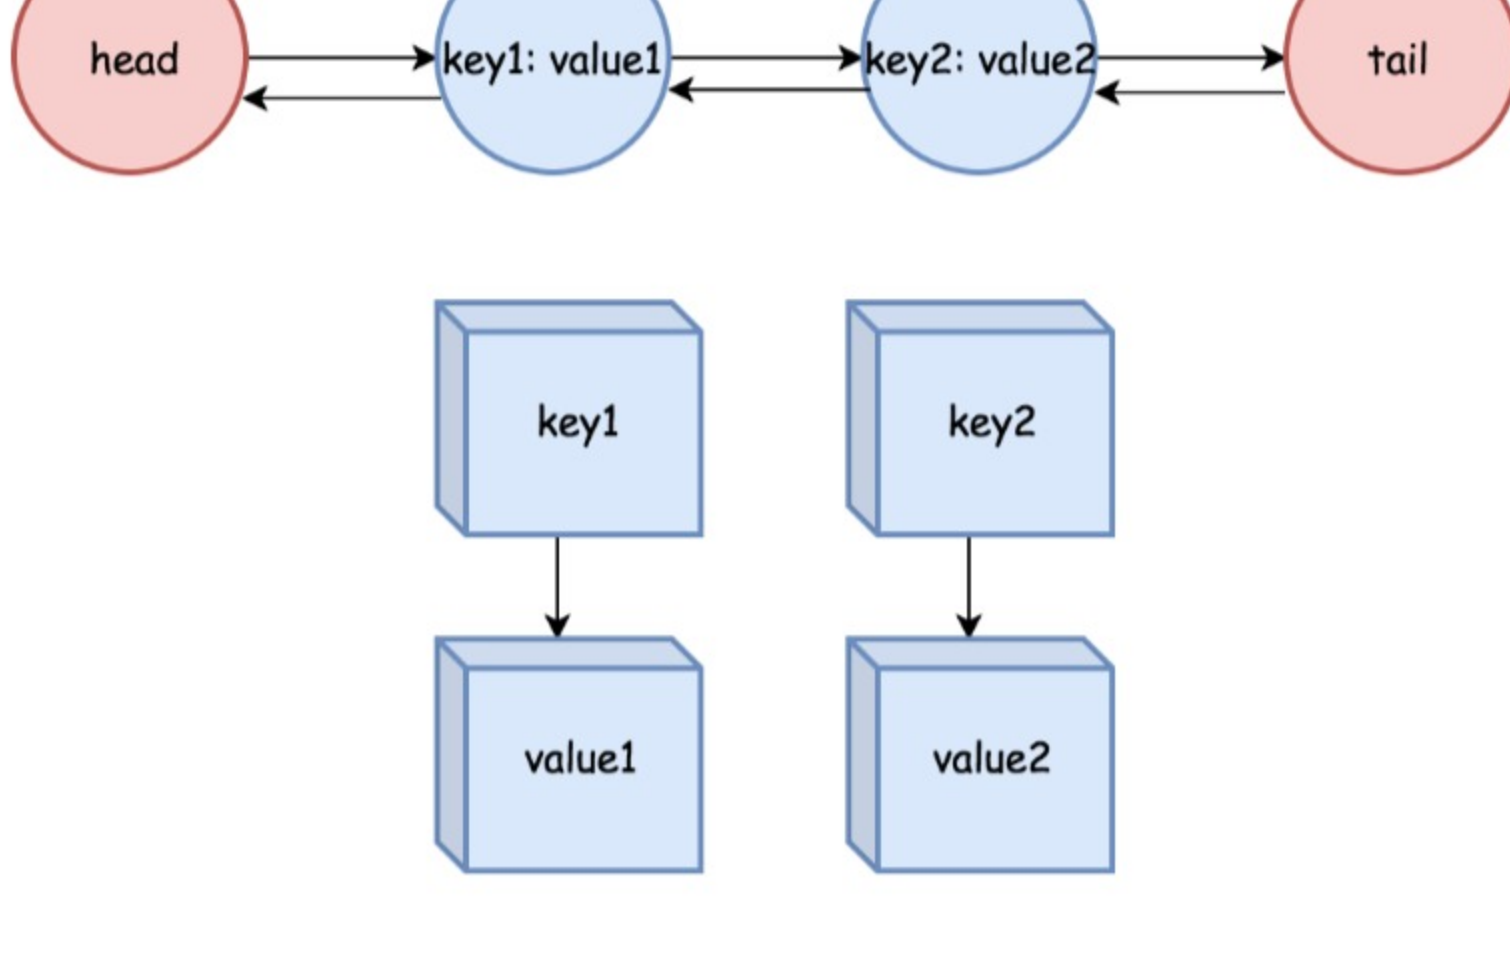

- Time complexity : $\mathcal{O}(1)$ both for `put` and `get` since all operations with ordered dictionary : `get/in/set/move_to_end/popitem` (`get/containsKey/put/remove`) are done in a constant time.
- Space complexity : $\mathcal{O}(capacity)$ since the space is used only for an ordered dictionary with at most `capacity + 1` elements.

Approach 2: Hashmap + DoubleLinkedList

Intuition

This Java solution is an extended version of the [the article published on the Discuss forum](#).

The problem can be solved with a hashmap that keeps track of the keys and its values in the double linked list. That results in $\mathcal{O}(1)$ time for `put` and `get` operations and allows to remove the first added node in $\mathcal{O}(1)$ time as well.

One advantage of *double* linked list is that the node can remove itself without other reference. In addition, it takes constant time to add and remove nodes from the head or tail.

One particularity about the double linked list implemented here is that there are *pseudo head* and *pseudo tail* to mark the boundary, so that we don't need to check the `null` node during the update.

Easy to add the node even in the empty list

Implementation

JavaPythonCopy

```
1 class DLinkedNode():
2     def __init__(self):
3         self.key = 0
4         self.value = 0
5         self.prev = None
6         self.next = None
7
8 class LRUCache():
9     def __add_node(self, node):
10        """
11        Always add the new node right after head.
12        """
13        node.prev = self.head
14        node.next = self.head.next
15
16        self.head.next.prev = node
17        self.head.next = node
18
19    def _remove_node(self, node):
20        """
21        Remove an existing node from the linked list.
22        """
23        prev = node.prev
24        new = node.next
25
26        prev.next = new
27        new.prev = prev
```

Complexity Analysis

- Time complexity : $\mathcal{O}(1)$ both for `put` and `get`.
- Space complexity : $\mathcal{O}(capacity)$ since the space is used only for a hashmap and double linked list with at most `capacity + 1` elements.

Using an OrderedDict / LinkedHashMap to solve this problem in an interview setting is like using `::-1` / `reverse()` to solve how to reverse a string, yeah you got it right but is that what the interviewer is looking for?

The description explicitly states, **Set or insert the value if the key is not already present**. And yet our solution must insert/update values when the key is already present. Am I the only person bothered by this apparent contradiction?

I'd find a much better explanation and solution from the discussion section.

Java Solution. Not a huge fan of the code proposed for solution #2. Here is a more straight forward code (same approach, just cleaner code).

```
class Node {
    // ...
}
```

I really like the dummy head & tail technique. Much more simple implementation with those in place and really minimal extra memory overhead. I just spent an hour catching all the edge cases without them! I'm puzzled why my solution is slower than most - I presume most solutions are cheating and using an LinkedHashMap. I also suspect the performance numbers are based on unrealistically small sample sets.

why remove oldest? what if a cache is frequently used and the eldest the same time?

how come this question is **downgraded** as a medium question suddenly?

@KingXun good question! The key in DLinkedNode would help us to remove the node itself from the cache at the moment the node becomes *stale* and is removed along with the invocation of the function `popTail`. We need to keep the key *along* with the node itself, because when the node is removed, we are not blessed with the key from the caller of LRU cache.

I think the structure should be implemented with non data-structure types -- i.e. no Collections, or else what's the point???

Using HashMap is just stupid, while using doubly LinkedList is just overkill, like what's the point???

Hashtable in java? Seriously?!? And then these people are getting offers instead of the real engineers and write that code in production.
