21 Mainly I group and count equal rows. Look for rows that appear N times and that have N black pixels. If you find one, add N for each of its black columns that doesn't have extra black pixels (in other rows).

```
def findBlackPixel(self, picture, N):
    ctr = collections.Counter(map(tuple, picture))
    cols = [col.count('B') for col in zip(*picture)]
    return sum(N * zip(row, cols).count(('B', N))
               for row, count in ctr.items()
               if count == N == row.count('B'))
```
